OCTAL DEBUGGING PROGRAM WITHOUT FLOATING POINT

Program Library Write-up

DECUS No. 8/8S-83 A

ABSTRACT

This program is an on-line debugger which will communicate with the operator through the ASR-33 Teletype. It allows register examination and modification, octal dumping, binary punching, multiple simultaneous breakpoints, starting a program, and running at a particular location with preset AC and link. ODP is completely relocatable at the beginning of all pages except page zero, and is compatible with the PDP-5, the PDP-8, and the PDP-8/S.

REQUIREMENTS

1. Storage

The high version of ODP requires from location 7000 to 7577. The low version requires from 0200 to 0777. All versions will require three pages. Also, location 0002 is used for a breakpoint pointer to ODP.

2. Equipment

The standard PDP-8 package with ASR-33 Teletype are required. In addition, a high-speed punch is optional.

LOADING

1. Be sure the binary loader is properly in core. If not, examine the RIM loader, and read in the binary loader.
2. Load in program that needs attention via this loader.
3. Load ODP via binary loader.

USAGE

1. Set SR toggles to the value of starting address (7000 in high version, 0200 in low). Press load address. Then push start.
2. ODP will execute a CR/LF and is prepared to execute user commands.

RESTRICTIONS

1. Breakpointer register

On page zero register 0002 is used as a pointer to ODP. It should be avoided.

2. Overlap

The user must not use any of the three pages of core in use by ODP.

3. Status core

ODP will operate only within the memory field in which it resides.

OPERATION

1. Description

ODP is essentially a unified collection of short routines for handling various user commands. The user types a letter representing a particular command, and an octal number if that is appropriate. For example, to insert a breakpoint (an effective JMS ODP which will trap an instruction at a desired location) one need only type B, followed by the octal absolute value of the address where the trapped instruction lies. A special feature of ODP is that many breakpoints (up to 7) may be simultaneously in core with the trapped instruction preserved. For instructions that require an octal number to be typed, ODP will type a space immediately after it identifies the command. After most instructions, a CR/LF combination will be executed to signal completion of that command. All octal numbers are automatically terminated after four digits, but may be terminated earlier by ALTMODE. ODP ignores all irrelevant characters.

2. Summary of commands

O XXXX Open register XXXX. ODP types out contents.

I XXXX Insert in most recently opened register the number XXXX.

N Type out the location followed by the contents of the next register. May be followed by I command.

B XXXX Put a breakpoint at location XXXX.

A Examine AC register. May be modified by I instruction.

L Examine link register. May be modified by I instruction. A 0001 is a set link; a 0000 is an off link.

D XXXX XXXX Dump in octal the contents of XXX to XXXX inclusive. Four words are placed per TTY line.

- S XXXX Start (or go) at XXXX with AC and link equal to zero.
- R XXXX Go from XXXX, the same as S, but with AC equal to the value of A register, and link equal to the value of L register.
- C Continue from most recently encountered breakpoint. Trapped instruction is replaced and C program is continued from the location of the trapped instruction. The initial contents of the link and AC are that of the L and A registers respectively.
- J This must be carefully watched! It causes program control to jump to location 6000 where single-stepper, written by the author for an interpretive language, usually resides.
- P Binary punch requested. Computer halts. Further information is via the SR.

3. Notes on various commands

1. Open (O)

After the register is examined it is automatically closed. Hence the user cannot accidentally modify the contents, as with DDT, by typing a new command string while the register is still open.

2. Insert (I)

Sequential insertion is possible with ODP. That is, after one I instruction, say at location XXXX, typing another I will cause insertion at location XXXX+1, and so on.

3. Breakpoints (B)

Up to seven breakpoints may be placed in core at once. If the user attempts to place more than seven in core, then the computer will halt. The same result will occur if, upon encountering a breakpoint, ODP cannot find it listed in its internal table. When the trapped instruction is re-installed (by the C instruction) that breakpoint is eliminated from the table. Upon encountering a breakpoint, the contents of the AC link are preserved in the A and L registers for user examination, and ODP will execute a CR/LF combination to signal return to its control.

4. Go instructions (S, C, and R)

After recognizing an S, C, or R command, the computer will set the AC and link appropriately, then halt. This is in case the user should want to place the computer in the single-step mode after one of these instructions. If this should not be the case, merely depress the continue switch.

5. Binary Punch (P)

After the user typed a P, the computer will halt. There are several functions that the user must now handle through the SR.

- a. Put up bit 11 for high-speed punch, leave off for ASR-33 punch. Push continue to indicate the output mode.
- b. Set the SR to the octal value of the number of individual blocks that are to be punched with a single checksum. Push continue. Leader is punched.
- c. Set the SR to the initial address of the first block. Push continue. Set the SR to the final address in the first block. Push continue. That block, with an origin setting, is punched out in binary loader format. Punch is inclusive from initial to final location.
- d. For the next block, go through the same steps as outlined in (c) except with the new initial and final addresses, and continue in this way. When the last block has been punched, the checksum and trailer will be punched. A CR/LF will be executed and ODP will await further instructions.
- e. RIM format

To punch in RIM format, put the number of blocks equal to (octal), and use the address of one register as both the initial and final addresses for each block. When done punching, set SR to 7264, load address, and push continue. (Make sure the AC is clear). Trailer will be punched. For the low version, set SR to 0464 and proceed as above.

COMBINED DEBUGGING PACKAGE with FLOATING POINT

DECUS No. 8/8S-83 B

ABSTRACT

The Combined Debugging Package (CDP) consists of the Octal Debugging Program (ODP) by this author plus certain additions which will enable the user to debug in floating point interpretive mode. Additional instructions provided include the insertion of interpretive breakpoints and single-stepping. At present the package is located directly below the floating point package to leave the lower portion of the memory to the user. It may easily be relocated to any desired position. Two versions are available: one for the three word package and a second for the four word package.

REQUIREMENTS

The standard version of CDP requires cells 3600-4614, and is compatible with floating point packages A, B, C. It must be relocated to 3400 to accommodate package D, due to the presence of the output controller. The four word version occupies memory locations 4200-5221, and is compatible with two additional versions of the four word package: that with output controller and that with extended functions, both written by this author. All versions of CDP require in addition, cell 2 for breakpoints, and cells 5, 6, 7 as pointers to the input, output, and arithmetic packages respectively.

OPERATION

CDP is an on-line debugger with two modes: floating and machine. Transfer to floating mode is accomplished by typing F. Machine mode is entered by the instruction M. When CDP is initially started, it is in machine mode. While in M mode it behaves exactly as ODP, with the minor exception that the J instruction has been liquidated in favor of the F command.

When transfer to F mode has been accomplished, a new set of instructions are enabled. The command B YYYY will insert an interpretive breakpoint (code 0017) at location YYYY. The original instruction is preserved and can be replaced with the C or S command. There may be up to seven interpretive breakpoints in core. Interpretive breakpoints and machine breakpoints are stored on separate tables. Hence there will be no interference between them, and seven of each type may be in core simultaneously. Upon encountering a breakpoint, the contents of the floating accumulator (FAC) will be typed out in decimal, floating point format, and control is returned to CDP.

The user then has several alternatives. He may choose to single-step, interpretively. To do this he merely types S, and the trapped instruction is replaced and executed. After its completion of that one interpretive command the FAC is typed out. Another S will cause another step to be executed after which the FAC is typed out. This process may continue indefinitely, until the user attempts to single-step over a FEXT. In this case CDP will type an up-arrow " " and transfer automatically to M mode. Because the single-stepping process is accomplished by continually moving the breakpoint one ahead, after the last S instruction one breakpoint will remain. To eliminate that breakpoint and restore the lost instruction, one must use the C command as described below. If one single-steps over a FEXT, the instruction past the FEXT is lost, replaced by an 0017. That is the penalty for carelessness. Also, there must be at least two locations on the breakpoint table free (or no more than five breakpoints in core at one time) for the S instruction to operate properly.

Another alternative after encountering a breakpoint is to continue full speed. This is accomplished by the C instruction. The breakpoint is replaced with the original instruction and processing continues from that point. If the user placed a breakpoint on a FEXT, and then wants to C, an up-arrow will be typed and automatic transfer to M mode will take place. Unlike the S instruction, however, there is no residue breakpoint in this case.

A third alternative might be to transfer back to M mode. This is done by typing M. If for some reason the user is not sure of what mode he is currently in, he may type the letter of the mode he thinks he is in. If there is no CR/LF response by CDP, it means that he typed a character that was not recognized, and hence is in the mode typed. If a CR/LF occurs, it means the user guessed wrong, but a transfer has occurred placing him in the mode he thought he was in before. Automatic transfer takes place upon encountering a breakpoint. If CDP is in M mode, and a floating breakpoint is encountered, automatic transfer to F mode is effected, and vice-versa.

The following instructions are also available in F mode and retain the same meaning as in M mode: O, I, N, A, L, D, R, and P.

ADDITIONS TO COMBINED DEBUGGING PACKAGES
for
FLOATING EXAMINATION and MODIFICATION

An addition has been written for CDP which will enable the user to examine and modify floating point numbers in core. Versions are available for both three and four word packages.

Old commands that were deleted from F mode include O, N, and I. The O was changed to E, for examination. The meanings of the commands N and I have been changed, although the mnemonics remain the same. Below is a summary of new commands.

- E XXXX Output in decimal the contents of the floating point number whose exponent is held in XXXX and whose mantissa follows in sequential registers.
- I XXXX Insert a floating point number exponent of which will be placed at XXXX and whose mantissa will follow in sequential registers. The user types the decimal number following the command. Also, note that sequential insertion is possible.
- N Examine the next sequential floating point number. If working with the four word package, this would be the location of the last exponent plus four.

For all the above commands, the FAC is saved and replaced after execution. To examine the FAC, the user need only type E 44 followed by an ALT-MODE to terminate the number before four digits.

The additions require 50 (octal) locations and are located directly under CDP. Thus, new core requirements are the following:

3 WORD VERSION: 3530-4614
4 WORD VERSION: 4130-5221

Starting addresses remain unchanged. Also, the program assumes that location 5 contains 7400. Check on this before using the additional instructions. Listings follow.

/3 WORK PACKAGE
/JAMES RUTledge ... JULY 6, 1967

/ADDITIONS TO ODP TO HANDLE FLOATING
/POINT DEBUGGING. THIS PORTION IS
/PLACED BELOW THE FLOATING POINT
/PACKAGE. A FLOATING BREAKPOINT IS
/INTERPRETIVE F017. COMMANDS IN THIS
/MODE ARE: S-XXXX -BREAKPOINT,C -
/CONTINUE AFTER BREAKPOINT,REINSTATING
/TRAPPED INSTRUCTION,S-SINGLE STEP (OR
/EFFECTIVELY MOVE BREAKPOINT ONE AHEAD)
/AND M - JUMP BACK TO MACHINE MODE.
/ENTRY INTO FLOATING MODE IS EFFECTED BY
/THE COMMAND F IN NORMAL, MACHINE LANGUAGE
/DEBUGGING MODE. THE F COMMAND REPLACES THE
/FORMER J COMMAND IN ODP. IN F MODE, THE
/COMMANDS T,D,P,A,L,D,R, AND P HAVE THE SAME
/EFFECT AS IN M MODE.
/NOTE: TO BE COMPATABLE WITH PACKAGE D,
/THIS PROGRAM MUST BE RELOCATED TO 4200.

BEG2=5000
/JAMES ROTHMAN ... JULY 6, 1967

/4 WORD PACKAGE
 /ADDITIONS TO ODP TO HANDLE FLOATING
 /POINT DEBUGGING. THIS PORTION IS
 /PLACED BELOW THE FLOATING POINT
 /PACKAGE. A FLOATING BREAKPOINT IS
 /INTERPRETIVE 0017. COMMANDS IN THIS
 /MODE ARE: B XXXX -BREAKPOINT, C -
 /CONTINUE AFTER BREAKPOINT, REINSTATING
 /TRAPPED INSTRUCTION, S-SINGLE STEP (OR
 /EFFECTIVELY MOVE BREAKPOINT ONE AHEAD)
 /AND M - JUMP BACK TO MACHINE MODE.
 /ENTRY INTO FLOATING MODE IS EFFECTED BY
 /THE COMMAND F IN NORMAL, MACHINE LANGUAGE
 /DEBUGGING MODE. THE F COMMAND REPLACES THE
 /FORMER J COMMAND IN ODP. IN F MODE, THE
 /COMMANDS I,O,N,A,L,D,R, AND P HAVE THE SAME
 /EFFECT AS IN M MODE.
